

# Priming distributivity

## The case of adjectival predicates

Mora Maldonado  
(work with Emmanuel Chemla and Benjamin Spector)

Linguae  
May 17th - 2017

# Phenomena

## Transitive Mixed Predicates

*(1) Mora and Milica built a sand castle.*

### **Non-Distributive reading (Collective reading)**

Mora and Milica jointly built a single sand castle without each separately doing so.

### **Distributive reading**

Mora built a sand castle, Milica built another sand castle.

## Adjectival Mixed Predicates

*(2) The bags are heavy.*

### **Non-Distributive reading (Collective reading)**

The total weight of the bags is heavy without each bag being heavy.

### **Distributive reading**

The weight of each bag is individually heavy (and therefore the total weight is heavy as well)

# Phenomena

## Transitive Mixed Predicates

*(1) Mora and Milica built a sand castle.*

### **Non-Distributive reading (Collective reading)**

Mora and Milica jointly built a single sand castle without each separately doing so.

### **Distributive reading**

Mora built a sand castle, Milica built another sand castle.

## Adjectival Mixed Predicates

*(2) The bags are heavy.*

### **Non-Distributive reading (Collective reading)**

The total weight of the bags is heavy without each bag being heavy.

### **Distributive reading**

The weight of each bag is individually heavy (and therefore the total weight is heavy as well)

# Phenomena

## Transitive Mixed Predicates

(1) *Mora and Milica built a sand castle.*

### **Non-Distributive reading (Collective reading)**

Mora and Milica jointly built a single sand castle without each separately doing so.

### **Distributive reading**

Mora built a sand castle, Milica built another sand castle.

**distributivity results on covariation of castles!**

## Adjectival Mixed Predicates

(2) *The bags are heavy.*

### **Non-Distributive reading (Collective reading)**

The total weight of the bags is heavy without each being heavy.

### **Distributive reading**

The weight of each bag is individually heavy (and therefore the total weight is heavy as well)

**distributivity does not result in covariation!**

# Phenomenon I: Transitive predicates

(1) *Mora and Milica built a sand castle.*

## **Non-Distributive reading (Collective reading)**

Mora and Milica jointly built a single sand castle without each separately doing so.

## **Distributive reading**

Mora built a sand castle, Milica built another sand castle.

Covert distributive operator  $D$  (cf. *each* in English), which applies the predicate to each atomic member of the subject.

Mora and Milica  $D$  built a sand castle.

$$\forall x.(x \preceq_{AT} \text{Mora} \oplus \text{Milica}) \rightarrow \exists y.\text{sandcastle}'(y) \wedge \text{built}'(x, y)$$

- $D$  guarantees here the distributive entailment.
- $D$  allows covariation (variables and operators in the VP are applied to each member of the subject)

# Priming of distributivity with covariation

Does the distributive/non-distributive contrast give rise to priming effects?

*Maldonado, Chemla and Spector 2017*

Sentence-picture matching task

**Target**

# Priming of distributivity with covariation

Does the distributive/non-distributive contrast give rise to priming effects?

*Maldonado, Chemla and Spector 2017*

Sentence-picture matching task

**Primes (N-1)**

Two squares are connected to three circles.

Distributive  
prime

[... D ...]

Two squares are connected to three circles.

Non-distributive  
prime

[...  $\emptyset$  ...]

**Target**

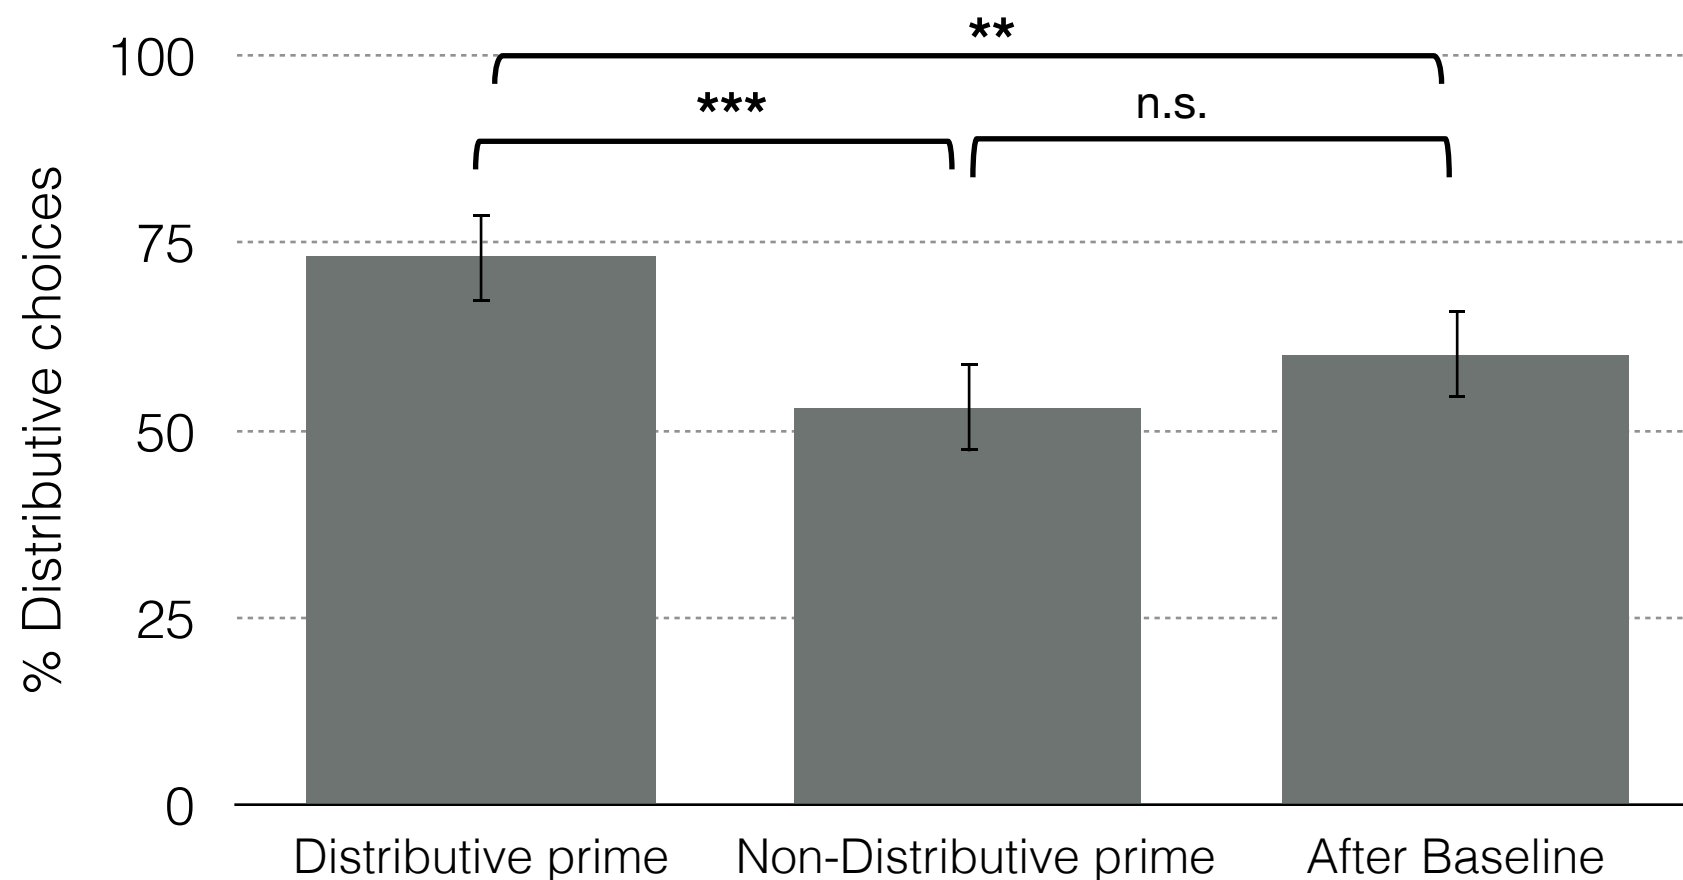

Two circles are connected to two hearts.

# Priming of distributivity with covariation

Does the distributive/non-distributive contrast give rise to priming effects?

*Maldonado, Chemla and Spector 2017*

**Target**

Two circles are connected to two hearts.

**Potential confound:** Dissociate priming of distributive readings from priming of a verification strategy involving covariation of the objects named in the sentence.

# Goal

## **Dissociate distributivity from covariation.**

Can we find a processing signature of distributive readings in absence of covariation?

- a. Remove potential confound in previous work.
- b. Address the relation between distributive readings and specific verification strategies.

# Phenomenon II: Adjectival predicates

(2) *The bags are heavy.*

## Collective reading

*The total weight of bags is heavy.*  
The plurality of bags is heavy without each of them being heavy.

## Distributive reading Collective reading

*Each bag is heavy, thus the total weight of bags is heavy.*  
The plurality of bags is heavy and each of them is heavy.

Distributive reading entails Collective reading.

# Phenomenon II: Adjectival predicates

(2) *The bags are light.*

**Distributive reading**

*The weight of each individual bag is light*  
Each bag is light without the plurality of bags being light.

**Distributive reading**  
**Collective reading**

*The total weight is light, thus the weight of each bag is light.*  
Each bag is light and the plurality of bags is light.

Collective reading entails Distributive reading.

Similar behaviour: Expensive/Cheap;  
Quiet/Noisy

# Phenomenon II: Adjectival predicates

	<b>Positive Adjective</b>	<b>Negative Adjective</b>
	<i>The bags are heavy.</i>	<i>The bags are light.</i>
Collective reading	Weak	Strong
Distributive reading	Strong	Weak

Distributive readings can also be derived by applying the  $D$  operator:

The bags  $D$  are light.

$$\forall x.(x \preceq_{AT} \iota x.bags'(x)) \rightarrow light'(x, y)$$

# Goal

## **Dissociate distributivity from covariation.**

Can we find a processing signature of distributive readings in absence of covariation?

Does the distributive/collective ambiguity for adjectival predicates give rise to priming effects?

- a. Remove potential confound in previous work.
- b. Address the relation between distributive readings and specific verification strategies.

- Overall interaction
- Collective prime vs. Distributive prime: Interaction Prime Condition\* Target Condition (rep. Exp1)
- Baseline-C vs. Distributive prime: Interaction Prime Condition\* Target Condition
- Baseline-D vs. Collective prime: Interaction Prime Condition\* Target Condition

# Discussion

- The distributive/collective contrast in sentences involving mixed predicates gives rise to priming effects:
  - New contrast in priming studies: collective vs. distributive readings.
  - Distributive readings can be primed independently of a verification strategy based on covariation.
- Priming effect in both directions (collective and distributive) but asymmetric strength (cf. previous studies)
- Semantic representations can be specifically primed independently of whether they give rise to strong or weak readings (i.e. weak distributive readings prime strong distributive readings)

# Follow-up

Are the mechanisms used to derive distributive readings the same in transitive and adjectival cases?

Can we prime distributivity *across* predicate types?

Thanks for your attention

## Collective Target

The bags are heavy.

## Distributive Target

The bags are light.

# Phenomenon I

## Transitive predicates: Distributivity with covariation

Applying the  $D$  operator does not force covariation. But, distributive readings can only be clearly isolated in covariation scenarios.

(1') *Mora and Milica painted a sand castle.*

Mora and Milica painted a sand castle.

$\exists y. \text{sandcastle}'(y) \wedge \text{painted}'(x, y)$

### Collective reading

Mora and Milica jointly painted a single sand castle without each separately doing so.

### Cumulative reading (assuming lexical cumulativity)

Mora and Milica painted the same sand castle.

Mora and Milica  $D$  painted a sand castle.

$\forall x. (x \preceq_{AT} \text{Mora} \oplus \text{Milica}) \rightarrow \exists y. \text{sandcastle}'(y) \wedge \text{painted}'(x, y)$

### Distributive reading with covariation (indefinite narrow scope, surface scope)

Mora painted a sand castle, Milica painted a potentially different sand castle.

### Distributive reading without covariation (indefinite wide scope, inverse scope)

Mora painted a sand castle, Milica painted the same sand castle.
